

# We need alternatives to antiretroviral therapy

Antiretroviral therapy (ART) keeps the amount of HIV virus in the bloodstream low for many people with HIV. However, ARTs must be taken daily, and some people develop resistance or permanent side effects to ARTs. To address the need for alternative treatment options, researchers at the National Institutes of Health (NIH) are conducting a clinical research study evaluating an investigational medication that may be an alternative to ART. Participants will be required to stop taking their ARTs during the study.

## **YOU MAY BE ABLE TO PARTICIPATE IF YOU:**

- Are ages 18 to 65
- Have HIV
- Are taking antiretroviral medications and are willing to interrupt your HIV treatment for at least 6 months

Participants will receive infusions of the investigational medication approximately once a month for about 6 months. After the 6 months, participants will re-start their ARTs and visit the study center once a month for another 6 months for follow up.

All study visits will take place at the NIH Clinical Center in Bethesda, Maryland. All volunteers will be compensated.
